Abstract: This standard specifies cryptographic transform and key archival methods for protection of data in sector-level storage devices.

Keywords: Security, Storage, Encryption, Key Management

Introduction

(This introduction is not part of IEEE P1619/D16, Draft Standard for Cryptographic Protection of Data on Block-Oriented Storage Devices.)

The purpose of this standard is to describe a method of encryption for data stored in sector-based devices where the threat model includes possible access to stored data by the attacker. The standard specifies the encryption transform and a method for exporting/importing encryption keys for compatibility between different implementations. Encryption of data in transit is not covered by this standard.

This standard defines the XTS-AES tweakable block cipher and its use for encryption of sector-based storage. XTS-AES is a tweakable block cipher that acts on data units of 128 bits or more and uses the AES block cipher as a subroutine. The key material for XTS-AES consists of a data encryption key (used by the AES block cipher) as well as a “tweak key” that is used to incorporate the logical position of the data block into the encryption. XTS-AES is a concrete instantiation of the class of tweakable block ciphers described in reference [XEX04]. The XTS-AES addresses threats such as copy-and-paste and dictionary attacks, while allowing parallelization and pipelining in cipher implementations.

Patents

Attention is called to the possibility that implementation of this standard may require use of subject matter covered by patent rights. By publication of this standard, no position is taken with respect to the existence or validity of any patent rights in connection therewith. The IEEE shall not be responsible for identifying patents or patent applications for which a license may be required to implement an IEEE standard or for conducting inquiries into the legal validity or scope of those patents that are brought to its attention.

Participants

The Security in Storage Working Group operated under the following sponsorship:

Sponsor: **John L. Cole, Information Assurance Standards Committee**
Co-Sponsor: **Curtis Anderson, Storage Systems Standards Committee**

When work on this draft standard began and until January 2007, the Security in Storage Working Group had the following officers:

James P. Hughes, Chair
Serge Plotkin, Vice-chair
Fabio Maino, Secretary

At the time this draft standard was completed, Security in Storage Working Group had the following officers:

Matthew V. Ball, Chair
Eric Hibbard, Vice-chair
Fabio Maino, Secretary

At the time this draft standard was completed, the P1619 Task Group had the following membership:

Serge Plotkin, Task Group Chair and Technical Editor

Gideon Avida
Matthew V. Ball
David L. Black
Russel Dietz
Rob Elliott
Hal Finney
John Geldman
Robert Griffin
Cyril Guyot
Shai Halevi

Laszlo Hars
Eric A. Hibbard
Larry D. Hofer
Walt Hubis
James P. Hughes
Glen Jaquette
Curt Kolovson
Robert A. Lockhart
Fabio Maino
Charlie Martin

David A. McGrew
Dalit Naor
Landon Curt Noll
Jim Norton
Scott Painter
David Sheehy
Robert N. Snively
Douglas L. Whiting

This document was edited by Serge Plotkin, Shai Halevi and Dalit Naor.
Special thanks to Doug Whiting, Brian Gladman, and Rob Elliott.

The following members of the balloting committee voted on this standard. Balloters may have voted for approval, disapproval, or abstention.

1 Standard for Cryptographic Protection of Data on 2 Block-Oriented Storage Devices

3 1. Overview

4 1.1 Scope

5 This standard specifies elements of an architecture for cryptographic protection of data on block-oriented
6 storage devices, describing the methods, algorithms, and modes of data protection to be used.
7

9 1.2 Purpose

10 This standard defines specific elements of an architecture for cryptographically protecting data stored in
11 constant length blocks. Specification of such a mechanism provides an additional and improved tool for
12 implementation of secure and interoperable protection of data residing in storage.

13 The XTS-AES transform defined in this standard is intended for encryption of storage where the threat
14 model includes possible access to stored data by the attacker, data to be protected is presented in fixed-size
15 units (sectors, logical disk blocks, etc.), and each unit must be processed separately, independently of other
16 data units. XTS-AES is a length-preserving transform, meaning that the ciphertext length produced by
17 XTS-AES is equal to the length of the plaintext. These two properties allow the use of XTS-AES as
18 transparent encryption: an encryption/decryption module may be added to an existing system without
19 having to modify the data layout of any of the existing components.¹

21
22 This standard includes the description of the XTS-AES transform itself (in both encryption and decryption
23 modes) and a specification of how it should be used for encryption of stored data. This standard also
24 contains a description of a key-export format. The goal is to facilitate a scenario where a standard-
25 conformant device that encrypts data using XTS-AES can export the key in a way that will allow
26 construction of another standard-conformant device that is able to import this key and decrypt the data.

27

28 1.3 Related work

¹ It is noted that the requirement for transparent encryption implies some inherent limitations on the level of security that can be achieved by such a transform, and these limitations should be carefully considered by an application that uses this standard.

1 The formal definition of the security goal of a tweakable block-cipher is due to Liskov, Rivest, and Wagner
 2 [LRW02], where they also show how tweakable ciphers can be built from standard block ciphers. An
 3 earlier work by Schroeppel suggested the idea of a tweakable block-cipher, by designing a cipher that
 4 natively incorporates a tweak [S98].

5 **2. References**

6 The following referenced documents are indispensable for the application of this document. For dated
 7 references, only the edition cited applies. For undated references, the latest edition of the referenced
 8 document (including any amendments or corrigenda) applies.

9 NIST FIPS-197, Federal Information Processing Standard (FIPS) for the Advanced Encryption Standard
 10 (AES).²

11 REC-xml, W3C Extensible Markup Language (XML) 1.0 (Fourth Edition). (<http://www.w3.org/TR/REC-xml/>).

13

14 **3. Definitions, acronyms and abbreviations**

15 **3.1 Definitions**

16 For the purposes of this standard, the following terms and definitions apply. *The Authoritative Dictionary*
 17 of IEEE Standards, Seventh Edition, should be referenced for terms not defined in this clause.
 19

20 **3.1.1 key scope:** Data encrypted by a particular key, divided into equal-sized data units (see 3.3). The key
 21 scope is identified by three non-negative integers: tweak value corresponding to the first data unit, the data
 22 unit size, and the length of the data.

23 **3.1.2 tweak value:** The 128-bit value used to represent the logical position of the data being encrypted or
 24 decrypted with XTS-AES.

25 **3.1.3 data unit:** Within IEEE Std 1619, 128 or more bits of data within a key scope. The first data unit in a
 26 key scope starts with the first bit of the key scope; each subsequent data unit starts with the bit after the end
 27 of the previous data unit. Data units within a key scope are of equal sizes. A data unit does not necessarily
 28 correspond to a physical block on the storage device.

29 **3.2 Acronyms and abbreviations**

30 AES	advanced encryption standard
31 DTD	document type definition
32 FIPS	Federal Information Processing Standard
33 GF	Galois field, see reference [Crypto-HBook].

² FIPS publications are available from the National Technical Information Service (NTIS), 5285 Port Royal Road, Springfield, VA 22661, USA. FIPS-197 is also available on-line from <http://csrc.nist.gov/publications/fips/index>.

1	LBA	logical block address
2	XML	extensible markup language
3	XTS	XEX encryption mode with tweak and ciphertext stealing
4	Base64	Encoding according to [RFC3548].

5 4. Special Terms

6 4.1 Numerical values

7 Decimal and binary numbers are used within this document. For clarity, decimal numbers are generally
8 used to represent counts and binary numbers are used to describe bit patterns.

9 Decimal numbers are represented in their usual 0, 1, 2, ... format. Binary numbers are represented by a
10 string of one or more bits followed by the subscript 2. Thus the decimal number 26 may also be represented
11 as 00011010₂.

12 4.2 Letter symbols

13 The following symbols are used in equations and figures:

14 \oplus Bit-wise exclusive-OR operation

15 \otimes Modular multiplication of two polynomials over the binary field GF(2), modulo
16 $x^{128}+x^7+x^2+x+1$, where GF stands for Galois Field (see [Crypto-HBook]).

17 α A primitive element of GF(2¹²⁸) that corresponds to polynomial x (i.e., 0000...010₂),
18 where GF stands for Galois Field (see [Crypto-HBook]).

19 \leftarrow Assignment of a value to a variable

20 $|$ Concatenation (e.g., if K1=001₂ and K2=101010₂, then K1|K2=001101010₂).

21 $//$ Start of a comment. Comment ends at end of line.

22 $\lfloor x \rfloor$ Floor of x (e.g. $\lfloor 7/3 \rfloor = 2$).

23

24 5. The XTS-AES transform

25 5.1 Data units and tweaks

26 This standard applies to encryption of data stream divided into consecutive equal-size data units, where the
27 data stream refers to the information that has to be encrypted and stored on the storage device. Information
28 that is not to be encrypted is considered to be outside of the data stream.
29

1 The data unit size shall be at least 128 bits. The number of 128-bit blocks in the data unit shall not exceed
 2 $2^{128}-2$. The number of 128-bit blocks should not exceed 2^{20} . Each data unit is assigned a tweak value which
 3 is a non-negative integer. The tweak values are assigned consecutively, starting from an arbitrary non-
 4 negative integer. When encrypting tweak value using AES, the tweak is first converted into a little-endian
 5 byte array. For example, tweak value $123456789A_{16}$ corresponds to byte array $9a_{16}, 78_{16}, 56_{16}, 34_{16}, 12_{16}$.

6
 7 The mapping between the data unit and the transfer, placement and composition of data on the storage
 8 device is beyond the scope of this standard. Devices compliant with this standard should include
 9 documentation describing this mapping. In particular, single data unit does not necessarily correspond to a
 10 single logical block on the storage device. For example, several logical blocks might correspond to a single
 11 data unit. Data stream, as used in this standard, does not necessarily refer to all of the bits sent to be stored
 12 in the storage device. In particular, if only part of a logical block is encrypted, only the encrypted bytes are
 13 viewed as the data stream, i.e. input to the encryption algorithm in this standard.

14 **5.2 Multiplication by a primitive element α**

15 The encryption and decryption procedures described in the following section use multiplication of a 16-
 16 byte value (the result of AES encryption or decryption) by j -th power of α , a primitive element of $GF(2^{128})$.
 17 The input value is first converted into a byte array $a_0[k]$, $k = 0, 1, \dots, 15$. In particular, the 16-byte result of
 18 AES encryption or decryption is treated as a byte array, where $a_0[0]$ is the first byte of the AES block.

19 This multiplication is defined by the following procedure.

20 Input: j is the power of α
 21 byte array $a_0[k]$, $k = 0, 1, \dots, 15$
 22 Output: byte array $a_j[k]$, $k = 0, 1, \dots, 15$

23 The output array is defined recursively by the following formulas where i is iterated from 0 to j :

24 $a_{i+1}[0] \leftarrow (2(a_i[0] \bmod 128)) \oplus (135 \lfloor a_i[15]/128 \rfloor)$
 25 $a_{i+1}[k] \leftarrow (2(a_i[k] \bmod 128)) \oplus \lfloor a_i[k-1]/128 \rfloor$, $k = 1, 2, \dots, 15$

26 Note - Conceptually, the operation is a left shift of each byte by one bit with carry propagating from one
 27 byte to the next one. Also, if the 15th (last) byte shift results in a carry, a special value (decimal 135) is xor-
 28 ed into the first byte. This value is derived from the modulus of the Galois Field (polynomial
 29 $x^{128}+x^7+x^2+x+1$). See Annex C for an alternative way to implement the multiplication by α^j .

35 **5.3 The XTS-AES Encryption Procedure**

36 **5.3.1 XTS-AES-blockEnc Procedure, Encryption of a Single 128-bit Block**

37 The XTS-AES encryption procedure for a single 128-bit block is modeled with this equation:

38 $C \leftarrow \text{XTS-AES-blockEnc}(Key, P, i, j)$
 39 where:
 40 Key is the 256 or 512 bit XTS-AES key
 41 P is a block of 128 bits (i.e., the plaintext)
 42 i is the value of the 128-bit tweak (see 5.1)
 43 j is the sequential number of the 128-bit block inside the data unit
 44 C is the block of 128 bits of ciphertext resulting from the operation

45 The key is parsed as a concatenation of two fields of equal size called Key_1 and Key_2 such that: $Key = Key_1 |$
 46 Key_2 .

1 The ciphertext shall then be computed by the following or an equivalent sequence of steps (see Figure 1):

- 2 1. $T \leftarrow \text{AES-enc}(\text{Key}_2, i) \otimes \alpha^j$
 3 2. $PP \leftarrow P \oplus T$
 4 3. $CC \leftarrow \text{AES-enc}(\text{Key}_1, PP)$
 5 4. $C \leftarrow CC \oplus T$

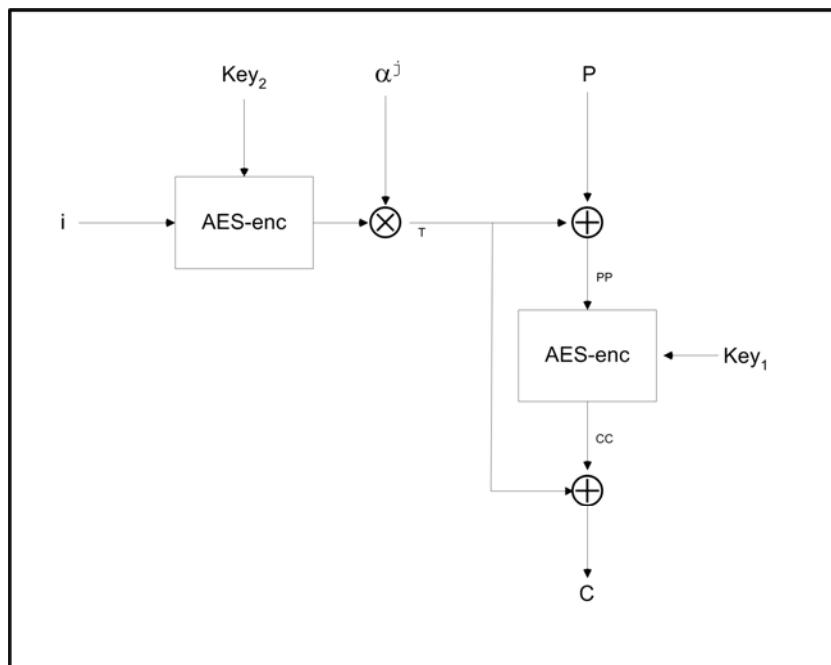

6

7 AES-enc(K, P) is the procedure of encrypting plaintext P using AES algorithm with key K , according to
 8 FIPS-197. The multiplication and computation of power in step 1 is executed in $\text{GF}(2^{128})$, where α is the
 9 primitive element defined in 4.2 (see 5.2).

10

11

Figure 1— Diagram of XTS-AES blockEnc procedure

12

13

14 5.3.2 XTS-AES Encryption of a data unit

15 The XTS-AES encryption procedure for a data unit of plaintext of 128 or more bits is modeled with this
 16 equation:

17 $C \leftarrow \text{XTS-AES-Enc}(\text{Key}, P, i)$

18 Where:

19 Key is the 256 or 512 bit XTS-AES key

20 P is the plaintext

21 i is the value of the 128-bit tweak (see 5.1)

22 C is the ciphertext resulting from the operation, of the same bit-size as P

23 The plaintext data unit is first partitioned into $m+1$ blocks:

24 $P = P_0 | \dots | P_{m-1} | P_m$

25 where m is the largest integer such that $128m$ is no more than the bit-size of P , the first m blocks P_0, \dots, P_{m-1}
 26 are each exactly 128 bits long, and the last block P_m is between 0 and 127 bits long (P_m could be empty, i.e.
 27 0 bits long). The key is parsed as a concatenation of two fields of equal size called Key_1 and Key_2 such that:
 28 $\text{Key} = \text{Key}_1 | \text{Key}_2$. The ciphertext C is then computed by the following or an equivalent sequence of steps:

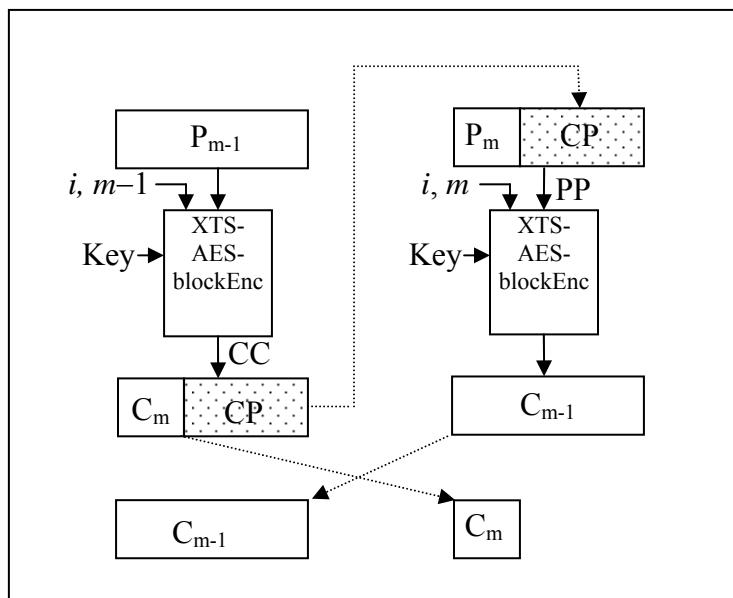

```

1       1.      for q ← 0 to m-2 do
2           a)    Cq ← XTS-AES-blockEnc(Key, Pj, i, q)
3           b)    b ← bit-size of Pm
4           if b=0 then do
5               a)    Cm-1 ← XTS-AES-blockEnc(Key, Pm-1, i, m-1)
6               b)    Cm ← empty
7           else do
8               a)    CC ← XTS-AES-blockEnc(Key, Pm-1, i, m-1)
9               b)    Cm ← first b bits of CC
10              c)    CP ← last (128-b) bits of CC
11              d)    PP ← Pm | CP
12              e)    Cm-1 ← XTS-AES-blockEnc(Key, PP, i, m)
13
14      5.      C ← C0 | ... | Cm-1 | Cm

```

15 An illustration of encrypting the last two blocks P_{m-1}P_m in the case that P_m is a partial block (b>0) is
16 provided in Figure 2.

17

18 **Figure 2—XTS-AES encryption of last two blocks when last block is 1 to 127 bits**19
20
2122 **5.4 The XTS-AES Decryption Procedure**23 **5.4.1 XTS-AES-blockDec Procedure, Decryption of a Single 128-bit Block**

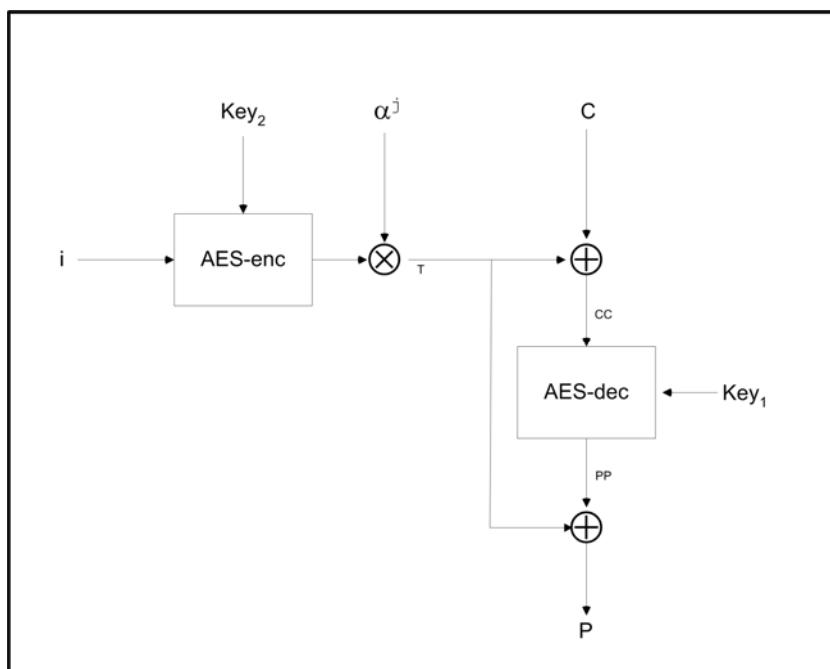

24 The XTS-AES decryption procedure of a single 128-bit block is modeled with this equation:

25 $P \leftarrow \text{XTS-AES-blockDec}(\text{Key}, C, i)$

26 where:

27 *Key* is the 256 or 512-bit XTS-AES key28 *C* the 128-bit block of ciphertext29 *i* is the value of the 128-bit tweak (see 5.1)30 *j* is the sequential number of the 128-bit block inside the data unit

1 P is the 128-bit block of plaintext resulting from the operation
 2 The key is parsed as a concatenation of two fields of equal size called Key_1 and Key_2 such that:
 3 $Key = Key_1 | Key_2$. The plaintext shall then be computed by the following or an equivalent sequence of steps
 4 (see Figure 3):
 5 1. $T \leftarrow AES\text{-enc}(Key_2, i) \otimes \alpha^j$
 6 2. $CC \leftarrow C \oplus T$
 7 3. $PP \leftarrow AES\text{-dec}(Key_1, CC)$
 8 4. $P \leftarrow PP \oplus T$
 9
 10 AES-dec(K, C) is the procedure of decrypting ciphertext C using AES algorithm with key K , according to
 11 FIPS-197. The multiplication and computation of power in step 1 is executed in $GF(2^{128})$, where α is the
 12 primitive element defined in 4.2 (see 5.2).
 13

14 **Figure 3—Diagram of XTS-AES blockDec procedure**15
1617 **5.4.2 XTS-AES Decryption of a Data Unit**18 The XTS-AES decryption procedure for a data unit ciphertext of 128 or more bits is modeled with this
 19 equation:20 $C \leftarrow XTS\text{-AES-Dec}(Key, C, i)$

21 where:

22 Key is the 256 or 512-bit XTS-AES key23 C is the ciphertext corresponding to the data unit24 i is the value of the 128-bit tweak (see 5.1)25 P is the plaintext data unit resulting from the operation, of the same bit-size as C 26 The ciphertext is first partitioned into $m+1$ blocks:

27
$$C = C_0 | \dots | C_{m-1} | C_m$$

1 where m is the largest integer such that $128m$ is no more than the bit-size of C , the first m blocks C_0, \dots, C_{m-1} are each exactly 128 bits long, and the last block C_m is between 0 and 127 bits long (P_m could be empty, i.e. 0 bits long). The key is parsed as a concatenation of two fields of equal size called Key_1 and Key_2 such that: $Key = Key_1 | Key_2$. The plaintext P is then computed by the following or an equivalent sequence of steps:

```

6   1. for q ← 0 to m-2 do
7       a)       $P_q \leftarrow \text{XTS-AES-blockDec}(\text{Key}, C_j, i, q)$ 
8   2. b ← bit-size of  $C_m$ 
9   3. if b=0 then do
10      a)       $P_{m-1} \leftarrow \text{XTS-AES-blockDec}(\text{Key}, C_{m-1}, i, m-1)$ 
11      b)       $P_m \leftarrow \text{empty}$ 
12 4. else do
13      a)       $PP \leftarrow \text{XTS-AES-blockDec}(\text{Key}, C_{m-1}, i, m)$ 
14      b)       $P_m \leftarrow \text{first } b \text{ bits of } PP$ 
15      c)       $CP \leftarrow \text{last } (128-b) \text{ bits of } PP$ 
16      d)       $CC \leftarrow C_m | CP$ 
17      e)       $P_{m-1} \leftarrow \text{XTS-AES-blockDec}(\text{Key}, CC, i, m-1)$ 
18 5.  $P \leftarrow P_0 | \dots | P_{m-1} | P_m$ 
```

19

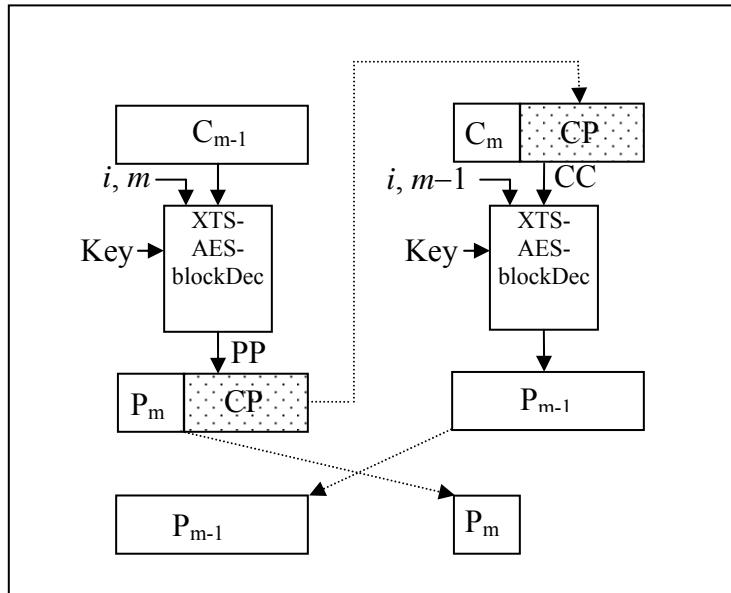

20 An illustration of the decrypting the last two blocks $C_{m-1}C_m$ in the case that C_m is a partial block ($b>0$) is
21 provided in Figure 4.

22

23 **Figure 4—XTS-AES decryption of last two blocks when last block is 1 to 127 bits**

24

25

26

6. Using XTS-AES-128 and XTS-AES-256 for Encryption of Storage

27

28 The encryption and decryption procedures described in 5.3.2 and 5.4.2 use AES as the basic building block.
29 If the XTS-AES key consists of 256 bits, the procedures use 128-bit AES; if XTS-AES key consists of 512
30 bits, the procedures use 256-bit AES. For completeness, the first mode shall be referred to as XTS-AES-
31 128 and the second as XTS-AES-256. To be compliant with the standard, the implementation shall support
at least one of the above modes.

1
2
3
4 Key scope defines the range of data encrypted with a single XTS-AES key. As defined in 7.1.4, the Key
5 Scope is represented by three integers: value of the tweak associated with the first data unit in the sequence
6 of data units encrypted by this key, the size in bits of each data unit, and the number of units to be
7 encrypted/decrypted under the control of this key. An implementation compliant with this standard may or
8 may not support multiple data unit sizes.
9

10 In an application of this standard to sector-level encryption of a disk, data unit typically corresponds to a
11 logical block, the key scope typically includes a range of consecutive logical blocks on the disk, and the
12 tweak value associated with the first data unit in the scope typically corresponds to the Logical Block
13 Address (LBA) associated with the first logical block in the range.
14

15 An XTS-AES key shall not be associated with more than one key scope. The reason is that encrypting more
16 than one block with the same key and the same index introduces security vulnerabilities that might
17 potentially be used in an attack on the system. In particular, key reuse enables trivial cut-and-paste attacks.
18

19 **7. Exporting and Archiving XTS-AES-128 and XTS-AES-256 keys**

20 **7.1 Key Backup Structure**

21 **7.1.1 Key Backup Structure Overview**

22
23 The system surrounding a device compliant with this standard should support the Key Backup structure
24 defined in this clause. XML representation of Key Backup structure is presented in 7.2. The Key Backup
25 structure provides all the information that is needed in order to decrypt an integral number of data units that
26 were encrypted with XTS-AES-[128,256]. These data units are assumed to be a contiguous sequence, with
27 a given tweak value (KeyScopeStart element in Table 4) associated with the first data unit.³ For example,
28 if the input data units are on a single physical medium, the initial tweak value can correspond to the first
29 data unit on this medium that is encrypted with the given XTS-AES-[128,256] key. Note that “size” field in
30 the following tables refers to the size of the element and not to the size of the encoding.

³ The inclusion of initial tweak value facilitates use of several different keys for a single physical medium. For example, each key can correspond to a different sequence of LBAs residing on a physical disk drive. Another situation where ability to specify initial tweak value is needed is when only part of encrypted data (contiguous sequence of data units starting at some offset) is archived together with the corresponding Key Backup structure. It is impossible to decrypt this data without knowledge of the initial tweak value i.e., the tweak value that corresponds to the first data unit in the archive.

1 Table 1 lists the elements of the key backup structure.

2

3 **Table 1 Key Backup Structure**

7 **7.1.2 Structure ID**

8 Table 2 defines the StructureID element, which contains the information needed to uniquely identify a
9 particular instance of a key backup structure.

10

Table 2 StructureID

Element	Size	XML Encoding	Description
ID	16 bytes	Base64	General identifier for the key backup structure.
Comment	Up to 1024 bytes	Text	A text description provided by the vendor.

11

12 **7.1.3 Standard**

13 Table 3 defines the Standard element, which contains information about the standard to which the data
14 units were encrypted.

15

Table 3 Standard

Element	Size	XML Encoding	Description
StandardNumber	Up to 128 bytes	Text	Number of the Standard used. Shall be IEEE STD 1619-2007.
StandardComment	Up to 256 bytes	Text	Any additional standard-related information.

16

17 **7.1.4 Key Scope**

18 The KeyScope specifies the scope of the key material that is identified in the key backup structure. The
19 KeyScope is an ordered sequence of data units, numbered consecutively starting at a certain position. Table
20 4 defines the KeyScope element.

1

Table 4 KeyScope

Element	Size	XML Encoding	Description
KeyScopeStart	16 bytes	Integer	Value of the tweak associated with the first data unit in the scope.
DataUnitSize	16 bytes	Integer	The number of bits in one data unit that is covered by the current key.
KeyScopeLength	16 bytes	Integer	The number of data units that are covered by the current key.

2

3 **7.1.5 Transform**

4 Table 5 defines the TransformName element.

Table 5 Transform

Element	Size	XML Encoding	Description
TransformName	Up to 16 bytes	Text	The transform name.

6

7 The transform name shall be one of the supported strings, as specified in Table 6 below.

8

9 **Table 6 Supported Transforms**

String	Description
XTS-AES-128	The XTS-AES-128 transform as defined in this standard.
XTS-AES-256	The XTS-AES-256 transform as defined in this standard.

10

11 **7.1.6 Key Material**

12 Table 7 defines the KeyMaterial element. All key material is secret.

Table 7 KeyMaterial

Element	Size	XML Encoding	Description
KeyLength	2 bytes	Integer	Length (in bits) of the key. Allowed values are 256 (for XTS-AES-128) and 512 (for XTS-AES-256).
KeyValue	variable	Base64	The value of the key.

14 **7.2 XML Format**

15 The Key Backup structure is encoded in XML, to facilitate a unified format and allow an application
 16 independent way of sharing key material. This also provides an automatic generation and parsing of Key
 17 backup structures. Document Type Definition (DTD) for Key Backup Format is shown in Figure 5.
 18

1 **7.3 Encryption of Key Backup material**

2 A Key backup structure may be protected as follows. The actual key material (KeyMaterial from Table 7)
3 shall be wrapped encrypted with xml-enc [XML-ENC, <http://www.w3.org/TR/xmlenc-core/>] and
4 embedded within the XML key backup structure. [XML-ENC] does not mandate any single key wrapping
5 algorithm, but implementations compliant with this standard shall support NIST AES CBC 256 (see
6 <http://www.w3.org/2001/04/xmlenc#aes256-cbc>). Other key wrap algorithms allowed by [XML-ENC] may
7 be used.

8
9 The keys that are used to wrap the key elements (KEK) may be referenced with xkms [XML-KMS]. The
10 location of wrapping keys is not specified by this standard. The cryptographic strength of wrapping keys
11 should be at least equivalent to the strength of the storage encryption keys wrapped (see reference [KEY-
12 MGMT]). For example, an AES-256 bit key should be used to wrap an XTS-AES-512 key. The
13 implementation should provide integrity for the key file, using standard methods.

14
15 In the example in Figure 7, the KeyMaterial is encrypted using AES-256 Key Wrap, whose wrapping key,
16 referenced by the KeyInfo element, has identifier “WrapKey”. (This xml example corresponds to the un-
17 wrapped example in Figure 6.)

18
19 Base64 encoding of the wrapping key used in the example is:
20 9s7VKp6PYKOXtYjs5OFBoqCDA3MmFd5tTqYnZv+PVro= .
21

1 Annex B

2 (informative)

3 Test Vectors

This Annex lists several examples of applying XTS-AES-128 and XTS-AES-256. All numbers in this Annex are hexadecimal. For readability, the examples explicitly parse the XTS-AES key into Key₁ and Key₂. All outputs are byte arrays (as opposed to hexadecimal numbers).

- PTX prefix denotes plaintext;
 - CTX prefix denotes ciphertext.
 - TWK prefix denotes the mask computed in step 1 in 5.3.1.

XTS-AES applied for a data unit of 32 bytes, 32 bytes key material.

69     }
}

```

1 **Annex D**

2 **(informative)**

3 **Rationale and Design Choices**

4 **D.1 Purpose**

5 This Annex provides some background material regarding design choices that were made in XTS-AES and
6 the rationale behind these choices.

7 **D.2 Transparent Encryption**

8 The starting point for this standard is a requirement that the transform be usable as transparent encryption.
9 That is, it should be possible to insert an encryption/decryption module into existing data paths without
10 having to change the data layout or message formats of other components on these data paths. In particular,
11 transparent encryption can be implemented to occur in the host, along the data path from host to storage
12 device, and inside the storage device, all without the need to modify the data transmission protocols or the
13 layout of the data on the media. In the context of encryption by sector-level storage devices, this
14 requirement translates into the following two constraints:

- 15 1. The transform must be *length-preserving*, namely the length of the ciphertext must equal that of
16 the plaintext. This means that the transform must be deterministic, and that it cannot store an
17 authentication tag along with the ciphertext.
- 18 2. The transform must be applicable to individual data-units (or sectors) independently of other data-
19 units and in arbitrary order. This means that no chaining between different data-units is possible.
20 This requirement stems from the need to support random access to the encrypted data. For
21 example, encryption mode that chains multiple data units requires reading of several data units to
22 decrypt a single unit.

23
24 Two solutions that were rejected by the group as insecure were to use either counter (CTR) mode or cipher
25 block chaining (CBC) mode, deriving the IV from the sector number.

- 26 • Using CTR without authentication tags is trivially malleable, and an attacker with write access to
27 the encrypted media can flip any bit of the plaintext simply by flipping the corresponding ciphertext
28 bit.
- 29 • For CBC, an attacker with read/write access to the encrypted disk can copy a ciphertext sector from
30 one position to another, and an application reading the sector off the new location will still get the
31 same plaintext sector (except perhaps the first 128 bits). For example, this means that an attacker
32 that is allowed to read a sector from the second position but not the first can find the content of the
33 sector in first position by manipulating the ciphertext.
- 34 • For CBC, an attacker can flip any bit of the plaintext by flipping the corresponding ciphertext bit of
35 the previous block, with the side-effect of “randomizing” the previous block.

36
37 The XTS-AES transform was chosen because it offers better protection against ciphertext manipulations
38 and cut-and-paste attacks. It is important to realize, however, that regardless of the method used for
39 encryption, the constraints above imply some inherent limitations on the level of security that can be

1 achieved by such transform. As shown below, these constraints imply that the best achievable security is
 2 essentially what can be obtained by using ECB mode with a different key per block (and using a cipher
 3 with wide blocks).

4
 5 Specifically, since there are no authentication tags then any ciphertext (original or modified by attacker)
 6 will be decrypted as some plaintext and there is no built-in mechanism to detect alterations. The best that
 7 can be done is to ensure that any alteration of the ciphertext will completely randomize the plaintext, and
 8 rely on the application that uses this transform to include sufficient redundancy in its plaintext to detect and
 9 discard such random plaintexts.

10
 11 Also, since this transform is deterministic, then encrypting the plaintext twice with the key and the same
 12 position will necessarily yield the same ciphertext. Moreover, since there is no chaining then an attacker
 13 can “mix and match” ciphertext units and get the same “mix and match” of their corresponding plaintext
 14 units. (Namely, if $C_0C_1\dots C_m$ is encryption of $P_0P_1\dots P_m$ and $C'_0C'_1\dots C'_m$ is encryption of $P'_0P'_1\dots P'_m$ then
 15 $C_0C'_1\dots C_m$ is encryption of $P_0P'_1\dots P_m$.)

16
 17 The above “mix and match” weakness can be mitigated to some extent by using some context information
 18 in the encryption and decryption processes. In the case of sector-level encryption, the only context
 19 information that can be assumed to be available at both encryption and decryption is the (logical) position
 20 of the current data unit (as seen by the encryption/decryption module).⁴ Incorporating the position
 21 information into the encryption and decryption routines makes it possible to cryptographically hide the fact
 22 that the same unit is written in two different places, and also prevents “mix and match” between different
 23 positions. But as mentioned above, even the best implementation of encryption by a sector-level storage
 24 device leaves several vulnerabilities. Three of these vulnerabilities are illustrated next.

- 25 • **Traffic analysis.** Consider an attacker that is able to passively observe the communication
 26 between the encrypting device and the disk. Since encryption is deterministic, this attacker is able to
 27 observe when a certain sector is written back to disk with a different value than was previously read
 28 from disk. This capability may help the attacker in mounting an attack based on traffic analysis.

- 29 • **Replay.** An attacker with read/write access to the encrypted disk can observe when a certain sector
 30 changes on the disk and then reset it to any one of its previous values. (Notice that this attack is not
 31 specific to transparent encryption, it may work even when using randomized encryption with
 32 authentication tags.)

- 33 • **Randomizing a sector.** Since there are no authentication tags, an attacker with write access to
 34 the encrypted disk can write an arbitrary ciphertext to any sector, causing an application that reads this
 35 sector to see a “random” plaintext instead of the value that was written to that sector. The behavior of
 36 the application on such “random” plaintext may be beneficial to the attacker.

37
 38 When using transparent encryption, one must therefore address these vulnerabilities by means outside the
 39 scope of this standard.

40 D.3 Wide vs. Narrow Block Tweakable Encryption

41 In light of the discussion above, the interfaces of the transform that is required are encryption and
 42 decryption routines:

$$43 \quad 44 \quad C = \text{Enc}(K, P, i) \text{ and } P = \text{Dec}(K, C, i), \\ 45$$

⁴ On the other hand, parameters like “time of encryption” cannot be used as context information, since the decryption procedure typically has no way of obtaining that information.

1 where the plaintext P and ciphertext C have the same length (i.e., the length of a single sector), K is the
 2 secret encryption key, and i represents the position information.

3
 4 The best security that one can hope for with such transform is that it looks to an attacker like a block cipher
 5 with block size equal to the sector size, and with different and independent keys for different values of i .
 6 Such a construct is called a “tweakable cipher” in the cryptographic literature. It was first defined formally
 7 by Liskov et al. in [LRW02].

8
 9 Several constructions that achieve these properties exist in the cryptographic literature (e.g., [HR03],
 10 [HR04], [H04], and a construction based on [NR98]). All these constructions, however, are rather
 11 expensive, requiring buffering of at least one sector worth of intermediate results and at least two passes
 12 over the entire sector.⁵ A cheaper alternative can be obtained by relaxing the requirement that the transform
 13 looks like a cipher with a wide (e.g. sector-length) block-size. Instead, one can work with narrow blocks of
 14 128 bits, but still insist that different blocks (whether in the same or in different sectors) look to an attacker
 15 like they were encrypted with different independent keys.

16
 17 Giving up the dependencies between different 128-bit blocks allows greater efficiency. The price for that,
 18 however, is that the attacks described in C.1 are now possible with better granularity. Namely, whereas the
 19 attacker against a wide-block encryption scheme can do traffic analysis or replay with granularity of one
 20 sector, the attacker against a narrow-block encryption scheme can work with granularity of 128-bit blocks.
 21 Still, the consensus in the group was the added efficiency warrants this additional risk. Since these risks
 22 exist even with wide-block encryption – albeit with a coarser granularity – then one would anyway need
 23 some other mechanisms for addressing them, and in many cases the same mechanisms can be used also for
 24 addressing these risks in their fine-grained form.

25

26 D.4 The XEX Construction

27 D.4.1 General XEX transform

28
 29 In [XEX04], Rogaway described a construction of a narrow-block tweakable cipher from a standard cipher
 30 such as AES. That construction works as follows: The tweakable cipher uses two keys, $K1$ and $K2$, both
 31 used as keys for the underlying cipher $\text{Enc}(K, \text{data})/\text{Dec}(K, \text{data})$. Given a plaintext block P and the tweak
 32 value, the tweak is parsed as a pair (s, t) (s can be thought of as the sector number and t as the block number
 33 within the sector). The construction first computes a mask value T using the following expression:

34
 35
$$T = \text{Enc}(K2, s) \otimes \alpha^t$$

36
 37 where the multiplication is in $\text{GF}(2^n)$ (with n being the block-size of the underlying cipher) and α is a
 38 primitive element of $\text{GF}(2^n)$. Given plaintext P , ciphertext C is produced by the following formula:

39
 40
$$C = \text{Enc}(K1, P \oplus T) \oplus T$$

41
 42 Given ciphertext C , the plaintext P is produced by the following formula:

43
 44
$$P = \text{Dec}(K1, C \oplus T) \oplus T.$$

45

⁵ At least some of this overhead appears to be inherent: Since these schemes insist on a block cipher with “wide block” (i.e., as wide as an entire sector), then every bit of ciphertext must “strongly depend” on every bit of plaintext and vice versa. This means in particular that no bit of output can be produced until all the input bits were processed by the block cipher.

1 D.4.2 Security of general XEX transform

The security analysis of generic XEX transform in [XEX04] shows that this mode is secure as long as the number of blocks that are encrypted under the same key is sufficiently smaller than the birthday bound value of $2^{n/2}$, where n is the block size in bits of the underlying block cipher. Some attacks become possible when the number of blocks approaches the $2^{n/2}$ value.,

The attacker analyzed in [XEX04] can make arbitrary encryption and decryption queries to the tweakable cipher, using arbitrary tweak values. These queries are answered either by the construction above, or by a truly random collection of permutations and their inverses over $\{0,1\}^n$ (a different, independent permutation for every value of the tweak), and the attacker's goal is to determine which is the case. Rogaway proved in [XEX04, Theorem 8] that an attacker that makes at most q such queries cannot distinguish these two cases with advantage more than $4.5 \frac{q^2}{2^n} + \varepsilon$ over a random guess (where ε is an error term that expresses the advantage of distinguishing the underlying cipher from a random permutation using q queries and n is the block size in bits of the underlying block cipher).

To explain the relevance of this analysis to the security of a real-world usage of the XTS-AES transform, we first argue that no realistic attacker would have more information than the attacker in the attack model that is described in the analysis. This follows from the fact that attacker in [XEX04] is assumed to be able to choose all the plaintext and ciphertext that is fed to the construction. Since the theorem [XEX04, Theorem 8] says that no attacker in that model can distinguish the construction from a collection of random permutations, it follows that no realistic attacker can distinguish between these cases with any significant advantage. This, in turn, means that whatever attack we are facing would be just as successful if we were using a collection of truly random permutations, one per each 128-bit block, to encrypt our data rather than using XEX.

It follows that when analyzing the security of an application that uses the above scheme, we can think of the encryption as if it was done using a collection of truly random 128-bit permutations. When faced with such a collection of truly random permutations, the only information that the attacker has is the following:

- The same plaintext with the same tweak value will always be encrypted to the same ciphertext (cf. the traffic analysis attack from above).
 - The same ciphertext with the same tweak value will always be decrypted to the same plaintext (cf. the replay attack from above).
 - Any other ciphertext (plaintext) will be decrypted (encrypted) to a random value (cf. the randomizing attack from above).

In other words, the proof in [XEX04] implies that except for the "error term" of $4.5 \cdot q^2/2^n + \varepsilon$, the only attacks that are possible against XEX are the ones that are inherent from the use of transparent encryption with the granularity of n -bit blocks, where n is the block size in bits of the underlying cipher.

Some attacks against XEX are possible when the number of blocks q approaches the birthday bound. For example, consider a known-plaintext attack where the attacker sees q tuples of tweak, plaintext, and ciphertext. For each such tuple $((s_i, t_i), P_i, C_i)$, denote by T_i the mask value that is computed from the tweak (s_i, t_i) .

From the birthday bound it follows that when q approaches $2^{n/2}$, there is a non-negligible probability that for some i, j there is a collision of the following form:

$$P_i \oplus T_i = P_i \oplus T_{i+}$$

In this case it also holds that:

$$C_i \oplus T_i \equiv \text{Enc}(K1, P_i \oplus T_i) \equiv \text{Enc}(K1, P_i \oplus T_i) \equiv C_i \oplus T_i$$

(Equation 1)

1 Summing these two equalities implies
 2
 3

$$P_i \oplus C_i = P_j \oplus C_j$$

6 This can be used to distinguish XEX from a collection of truly random permutations. The attacker
 7 computes for all i the sum $S_i = P_i \oplus C_i$ and counts the number of pairs (i, j) for which $S_i = S_j$. The argument
 8 above implies that for any i, j , the probability that $S_i = S_j$ in ciphertext produced by XEX is roughly
 9 $2^{-n} + 2^{-n} = 2^{-n+1}$, where the first term is due to collision between i and j and the second term is due to equality
 10 $S_i = S_j$ without a collision. On the other hand, for truly random permutation the probability of $S_i = S_j$ is exactly
 11 2^{-n} , and hence after observing roughly $2^{n/2}$ tuples $((s_i, t_i), P_i, C_i)$ it is possible to distinguish ciphertext
 12 produced by XEX from a random sequence with non-negligible probability.

13 Given a collision between i and j as above, the following approach shows how the attacker can use his
 14 ability to create legally encrypted data for position i and ability to modify ciphertext in position j to modify
 15 the ciphertext at j so it will decrypt to an arbitrary attacker-controlled value.
 16

18 As above, the attacker begins by computing the sums $S_i = C_i \oplus P_i$ and uses any equality $S_i = S_j$ as an evidence
 19 of collision between i and j . Denote by $((s_i, t_i), P_i, C_i), ((s_j, t_j), P_j, C_j)$ the corresponding tweak, plaintext, and
 20 ciphertext values.

22 For some $\Delta \neq 0$, the attacker encrypts a new value $P'_i = P_i \oplus \Delta$ in position (s_i, t_i) , observes the corresponding
 23 ciphertext C'_i , and replaces the ciphertext block C_j by:

$$C'_j = C_j \oplus (C_i \oplus C'_i).$$

27 This new ciphertext block will be decrypted as $P'_j = P_j \oplus \Delta$. In other words, the attacker succeeded in
 28 “flipping” specific bits in plaintext corresponding to location j . To see this, observe that:

$$\begin{aligned} C'_j \oplus T_j &= C_j \oplus (C_i \oplus C'_i) \oplus T_j && \text{(Equation 2)} \\ &= C'_i \oplus (C_i \oplus C_j) \oplus T_j \\ &= C'_i \oplus (T_i \oplus T_j) \oplus T_j && \text{(follows from Equation 1)} \\ &= C'_i \oplus T_i \end{aligned}$$

35 Therefore:

$$\text{Dec}(K1, C'_j \oplus T_j) = \text{Dec}(K1, C'_i \oplus T_i)$$

39 which implies that:

$$\begin{aligned} P'_j &= T_j \oplus \text{Dec}(K1, C'_j \oplus T_j) \\ &= T_j \oplus \text{Dec}(K1, C'_i \oplus T_i) && \text{(follows from Equation 2)} \\ &= (T_j \oplus T_i) \oplus [T_i \oplus \text{Dec}(K1, C'_i \oplus T_i)] \\ &= (T_j \oplus T_i) \oplus P'_i \\ &= (T_j \oplus T_i) \oplus (P_i \oplus \Delta) \\ &= ((T_j \oplus T_i) \oplus P_i) \oplus \Delta \\ &= P_j \oplus \Delta. \end{aligned}$$

50 D.4.3 XTS-AES as a specific instantiation of general XEX

51 The XTS-AES-128 and XTS-AES-256 transforms described in this standard are concrete instantiations of
 52 the XEX scheme with AES as the underlying block cipher, and thus using $n=128$ as the block length. A
 53 data unit sequence number (i.e., relative position) is used as a tweak in order to allow for copy or backup of

1 a key scope or partial key scope of data encrypted with XTS-AES-[128,256] without re-encryption. In
 2 contrast to the generic XEX construction described in [XEX04] that uses a single key, the XTC-AES-128
 3 and XTS-AES-256 modes in this standard use separate keys for tweaking and encryption purposes. This
 4 separation is a specific example of separation of key usage by purpose and is considered a good security
 5 design practice (see [KEY-MGMT, part 1, Section 5.2]).

6
 7 The expression $4.5 q^2/2^n$ is small enough as long as q is not much more than 2^{40} . The proof from [XEX04]
 8 yields strong security guarantee as long as the same key is not used to encrypt much more than a terabyte of
 9 data (which gives $q=2^{36}$ blocks). For this case, no attack can succeed with probability better than 2^{-53} (i.e.,
 10 approximately one in eight quadrillion).

11
 12 This security guarantee deteriorates as more data is encrypted under the same key. For example, when
 13 using the same key for a petabyte of data, attacks such as in D.4.2 have success probability of at most
 14 approximately 2^{-37} (i.e., approximately eight in a trillion), and with exabyte, of data the success probability
 15 is at most approximately 2^{-17} (i.e., approximately eight in a million).

16
 17 The decision on the maximum amount of data to be encrypted with a single key should take into account
 18 the above calculations together with the practical implication of the described attack, (e.g. ability of the
 19 attacker to modify plaintext of a specific block, where the position of this block may not be under attacker's
 20 control).

21 **D.5 Sector-size that is not a multiple of 128 bits**

22 The generic XEX transform as described in [XEX04] immediately implies a method for encrypting sectors
 23 that consist of an integral number of 128-bit blocks: apply the transform individually to each 128-bit block,
 24 but use the block number in the sector as part of the tweak value when encrypting that block. This method
 25 is applicable to the most common sector sizes (such as 512 bytes or 4096 bytes). However, it does not
 26 directly apply to sector sizes that are not an integer multiple of 128-bit blocks (e.g., 520-byte sectors).

27
 28 To encrypt a sector which length is not an integral number of 128-bit blocks, the standard uses the
 29 "ciphertext-stealing" technique similar to the one used for ECB mode (see [MM82, Fig. 2-22]). Namely,
 30 both XTS-AES-128 and XTS-AES-256 encrypt all the full blocks except the last full block (with different
 31 tweak values for each block), and then encrypt the last full block together with the remaining partial block
 32 using two application of the XTS-AES-blockEnc procedure described in 5.3.1 with two different tweak
 33 values, as described in 5.3.2.

34 **D.6 Miscellaneous**

35 Following are general remarks about appropriate use of the XTS-AES transform.

- 36 • When analyzing the security of an application that uses this standard, one must consider the methods
 37 that were used to generate the keys. As with every cryptographic algorithm, it is important that the
 38 secret-key used for XTS-AES-[128,256] be chosen at random (or from a "cryptographically strong"
 39 pseudo-random source). Indeed, all security guarantees (including the security claims of the theorem
 40 from [XEX04]) are null and void if the key is chosen from a low entropy source. The issues of strong
 41 pseudo-randomness and key-generation are outside the scope of this standard. For further information,
 42 see [KEY-MGMT].
- 43 • Use of a single cryptographic key for more than a few hundred terabytes of data opens possibility of
 44 attacks, as described in D.4.3. The limitation on the size of data encrypted with a single key is not
 45 unique to this standard. It comes directly from the fact that AES has a block size of 128 bits and is not
 46 mitigated by using AES with a 256-bit key.
